Stream: BTech
Year of graduation: 2028

Nihar R. Das

College: Indian Institute of
Technology, Patna
Stream: BTech
Year of graduation: 2028

Describe the problem statement (200 words)

Every modern business runs on dashboards. Revenue is up 5%, conversion is down 2%, or a region's sales suddenly drop 8%. But a dashboard's job stops at showing **what changed**. It rarely tells you **why**.

The real work starts after the dashboard. Analysts manually dig through **order data, marketing reports, and customer feedback**, cross-check timelines, and look for connections. This can take days, and the result is often a plausible explanation rather than a **systematic, evidence-backed investigation**.

The delay has a real cost. Businesses spend valuable time **not knowing what is wrong**, making it harder to respond quickly and confidently. Understanding why a metric changed remains slow, manual, and dependent on having the right person available to investigate.

The deeper problem is that the two halves of the story are usually separated. **Orders, traffic, and revenue** live in structured systems, while **reviews, complaints, and support tickets** contain the human context elsewhere. These sources rarely come together, leaving analysts to piece together **half the picture at a time**.

In short: businesses have more data than ever, but turning it into a **clear, trustworthy explanation** still requires slow, manual detective work every time a number moves.

Proposed solution (200 words)

The “Why” Behind the Number

When a KPI changes, our system starts by breaking down **what actually moved**. It looks across dimensions such as **region, product, customer, and time** to understand where the change is concentrated.

It then brings together the **context that usually sits outside the dashboard**. Orders, traffic, and product data are analyzed alongside **customer reviews, support tickets, internal comments, and other business text** to find signals that moved around the same time and in the same context.

Finally, the system connects these signals and presents the **strongest likely factors** with the **evidence behind them**. It does not claim to know what caused the change. Instead, it gives the analyst a **clear, evidence-backed starting point** for deciding **what to investigate next**.

Proposed Architecture

From Enterprise Data to Evidence-Backed Decisions

An evidence-driven intelligence architecture

Thank you
